A 42-year-old woman with no vascular risk factors was admitted with neck pain and right Horner syndrome after riding a roller coaster. Magnetic resonance imaging (MRI) of her neck showed a characteristic crescent-shaped intramural haematoma in the right internal carotid artery (Figure, A), confirmed by magnetic resonance angiogram (MRA) (Figure, B). T1-fat-suppressed MRI and arterial wall imaging are currently the most sensitive techniques for diagnosis of dissection. Riding roller coasters has been associated with shearing neck injury leading to cervical artery dissection.2 Our patient was treated with warfarin for 6 months, leading to the intramural haematoma resolving and the Horner syndrome greatly improving.
